Disaster Recovery Runbook

Document ID: DOC-004

Owner: Site Reliability Engineering

Status: Active

Version: 5.0

Last Updated: 2025-11-18

Environment: Production

Purpose

This runbook describes the recovery process for critical NexusScale production workloads following a regional or platform-level failure.

Recovery Sources

The disaster recovery process relies on the centralized backup repository as the primary source for restoring persistent production data.

Recovery operators should select the most recent verified recovery point that is consistent with the incident timeline.

Recovery Window

The centralized recovery repository maintains restorable snapshots for critical production databases covering the previous ninety days.

Snapshots within this period are available for disaster recovery operations unless explicitly excluded by legal retention requirements.

Recovery Validation

Before restoring customer-facing workloads, the recovery operator must verify backup integrity, confirm the selected recovery point, validate encryption key availability, and obtain approval from the incident commander.

Post-Recovery

Following restoration, the service owner must validate application health and data consistency before normal traffic is restored.
